**Kodak Duplicating Microfilms**

*Kodak Duplicating Microfilms* are silver-halide films designed for making high quality duplicates of original camera and other duplicate microfilms. Depending on the film type used, these films can either maintain or reverse image polarity. These duplicating microfilms can be used in a variety of manufacturer’s silver duplicators. *Kodak Duplicating Microfilms* are fine grain, high resolution microfilms with the exposure and development latitude to duplicate/enhance varying quality originals.

Information regarding the following duplicating microfilms are included in this document:

- *Kodak Duplicating 2462 Microfilm*
- *Kodak Direct Duplicating 2468/3468 Microfilm*
- *Kodak Direct Duplicating Intermediate 2470 Microfilm*

**Product applications**

*Kodak Duplicating* and *Direct Duplicating Microfilms* are primarily intended for creating multiple distribution copies of camera film masters, and occasionally as intermediate print film masters, when creating large quantities of duplicates such that the original camera film is not at risk of damage. *Kodak Direct Duplicating Intermediate Microfilm* is typically used as an intermediate print master but may also be used as a distribution copy. All duplicating microfilms use a “contact-printing” method, such that the master and duplicate are brought into intimate contact during exposure. A description of each follows.
**Kodak Duplicating Microfilm — 2462**

- Reverses image polarity (neg-to-pos or pos-to-neg) with conventional processing
- Blue spectral sensitivity
- Medium contrast
- Primarily used for making positive images of publications such as newspapers and magazines for frequent viewing

**Kodak Direct Duplicating Microfilm — 2468/3468**

- Maintains image polarity (neg-to-neg or pos-to-pos) with conventional processing
- Orthochromatic color sensitivity (blue-green)
- Medium contrast
- Primarily used for making distribution copies

**Kodak Direct Duplicating Intermediate Microfilm — 2470 (Estar Base)**

- Maintains image polarity (neg-to-neg or pos-to-pos) with conventional processing
- Orthochromatic color sensitivity (blue-green)
- Excellent tone reproduction
- Medium - low contrast
- Primarily used as an intermediate master to make multiple generation copies
- Can also be used as a distribution copy

**Microfilm thicknesses**

Kodak silver-halide duplicating microfilms are available in the following thicknesses:

- **2462 and 2468 Estar Base 4.0 mil** — used in normal 16, 35 and 105 mm roll film applications.
- **3468 Estar Thin Base 2.5 mil** — used in 16 mm applications for reduced loading frequency, reduced film storage requirements and maximum image capacity per roll.
Common features

The following features are common to all Kodak Duplicating Microfilms:

- Life expectancy of 500 years (LE-500) when processed and stored properly, compared with 100 years (LE-100) for nonsilver duplicating films such as diazo and vesicular.
- Ultra-high resolving power.
- Static-resistant, process-survivable backing.
- Micro-fine granularity.
- Very slow speed.
- Manufactured process is registered to ISO 9000.
- Manufactured to ANSI and ISO standards specifications for films to be used for storing records of long-term or permanent value.

The following “duplication tree” illustrates how the various duplicating microfilms are used to produce the desired contrast and image polarity of distribution copies. As an example, 3N is showing 3rd generation negative-appearing distribution copies.

KEY:

CN = Camera Negative
1 = 1st generation
2 = 2nd generation
3 = 3rd generation
N = Negative polarity
P = Positive polarity

Exposure

The following table indicates values for 1/25-second tungsten exposures calculated using the formula 45/H, where H is the exposure in lux-seconds required for a density of .10 (1.20 for 2462 Microfilm) above minimum density with indicated processing. This number can be used directly with incident-light meters.

</tr>
<tr>
<td>2470</td>
<td>0.12</td>
</tr>
</tbody>
</table>

Reciprocity data

For the Direct Duplicating Microfilms (2468/3468 and 2470), tungsten exposures from 100 to 0.001 seconds, and processing in a Kodak Prostar Processor as recommended, reciprocity failure is negligible and no correction is normally needed. Similar results are expected with other recommended processes.

With Duplicating Microfilm 2462 and using other than 1/50-second tungsten exposures, correct for reciprocity failure at a density of 1.20 above D-min as follows:

<table>
<thead>
<tr>
<th>Microfilm</th>
<th>Exposure Time (seconds)</th>

*for Kodak Prostar Processor and continuous strand.
Exposure guidelines — 2468/3468 and 2470
Print density decreases with increased exposure and increases with added
development for the direct duplicating microfilms. For intermediate duplicating
masters, generally the D-min in the master should be printed to the density in
the following table. 2470 Microfilm is generally not used for distribution copies.
If it is used as a distribution copy, reduce D-min levels to the levels indicated
for 2468/3468 Microfilm.

<table>
<thead>

Processing information

Processors and processing chemicals
Kodak Duplicating Microfilms can be processed in most typical continuous-
strand type medium- and deep-tank processors using common Kodak
Processing Chemicals and parameters. They are compatible with all standard
microfilm processing equipment and high quality microfilm chemicals, although
results may vary.

IMPORTANT: For best results and to avoid aeration, always add chemical 
concentrate to water, not water to concentrate.

Processor set up
Following are the specifications for all Kodak Duplicating Microfilms. These are
the starting points and mixed formats.

<table>
<thead>
<tr>
<th>Conventional Processor</th>
<th>Developer Dwell</th>
<th>Developer Temp</th>
<th>Fixer Dwell</th>
<th>Fixer Temp</th>
<th>Wash Temp</th>
<th>Dry Temp</th>
<th>Dilution</th>
<th>Dev</th>
<th>Fix</th>

<td>71.1°C</td>
<td>1:7</td>
<td>1:3</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: The dwell times and temperatures are starting points only. Specific
systems or customer needs may demand variation from these values
based on photographic aims. Dwell time is determined by timing film
speed from entrance roller to exit roller while running in the processor.
Deep tank times given should match the photographic results of a
Prostar Processor; significantly shorter development times are
achievable with these films by using higher exposure conditions
without any detriment to image quality.

* For 2462 Microfilm, the starting dwell time for the developer is 68 seconds.
Replenishment rates

Development/transport time and transport rates are set to achieve desired photographic aims; replenishment rate settings are determined by multiplying the transport speed by the required replenishment rates for the appropriate film width being used.

Use the chart and formula provided to determine the developer and fixer replenishment rates (mL/min) by multiplying transport speed (ft/min) (which is determined by dividing the path length of the developer tank in feet by the dwell time in seconds and multiplying by 60; see example) and the appropriate processor replenishment specification (mL/linear ft).

### Replenishment mL/linear ft

<table>
<thead>
<tr>
<th></th>
<th>16 mm</th>
<th>35 mm</th>
<th>105 mm</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Dev</td>
<td>Fix</td>
<td>Dev</td>
</tr>
<tr>
<td><strong>Kodak Prostar</strong></td>
<td>0.75</td>
<td>0.75</td>
<td>1.5</td>
</tr>
<tr>
<td><strong>Deep Tank</strong></td>
<td>1.00</td>
<td>1.25</td>
<td>2.0</td>
</tr>
</tbody>
</table>

**NOTE:** These are starting point recommendations. Actual settings may require adjustments to maintain process activity levels. Shorter dwell times are acceptable; however, exposure adjustments will be necessary.

### A calculation of replenisher rate follows:

For Processor: Allen M-70 Processor

Type of Film: 35 mm (2468 Microfilm)

Dwell: 70 seconds

Developer Film Path: 84 feet

Replenishment (Dev): 2 (from table above)

Calculated transport speed:

\[
\frac{84 \text{ ft}}{70 \text{ sec}} \times 60 \text{ sec/min} = 72 \text{ ft/min}
\]

**Results:**

\[
72 \text{ ft/min} \times 2 \text{ mL/ft} = 144 \text{ mL/min}
\]

replenishment rate for developer
Before-process handling and storage

Handling

Total safelight exposure, whether before or after image exposure, should not exceed 30 minutes. For darkroom handling, 2468/3468 and 2470 Microfilms should use a Kodak 1 Safelight Filter / red or Kodak 2 Safelight Filter / dark red, in a suitable safelight lamp with a 15-watt bulb, located at least 4 feet (1.2 meters) from the film. Use a Kodak OA Safelight Filter / greenish yellow, with the same lamp distance conditions for 2462 Microfilm. When using gooseneck lamps with contact printers, a Kodak 1 Safelight Filter / red is required.

Storage

For optimum life of Direct Duplicating Microfilms (2468/3468 and 2470), keep unopened packages at 55°F (13°C), at 50 percent relative humidity or below, and protected from radiation and x-rays. Film stored at higher temperatures or humidities for a period of six months or more may lose photographic speed or D-max. Duplicating Microfilm (2462) can be stored at 70°F (21°C) at 50 percent relative humidity or below, and protected from radiation and x-rays. To avoid moisture condensation on film that has been refrigerated, allow cold film to reach approximate room temperature before opening the package (about 3 hours if refrigerated, 5 hours if frozen).

After-process and storage information

Image stability and keeping

These microfilms are manufactured to ANSI and ISO specifications for extended term storage use. When processed as recommended, these microfilms meet both ANSI and ISO specifications for microfilms intended for long-term storage. These microfilms have a Life Expectancy LE-500 rating.

ISO 19801 2002, Photography — Processed Silver-Gelatin Type Black-and-White Film — Specifications for Stability, state that the maximum permissible concentration of thiosulfate ion is 0.014 grams per square meter (1.4 micrograms per square centimeter). Thiosulfate limits for Class 1 grain apply to this microfilm.

ANSI ISO 18911 2000, Photography — Processed Safety Photographic Films-Storage Practices, gives appropriate conditions for extended term (permanent) and long-term storage films. Information is also available in Kodak Publication D-31, Storage and Preservation of Microfilms. Extended term storage conditions require a temperature of less that 70°F (21°C) and 20- to 50-percent RH for polyester base microfilm.

These ANSI/ISO Standards can be obtained by contacting: Association for Information and Image Management International (AIIM), 1100 Wayne Avenue, Suite 1100, Silver Spring, MD 20910-5603, website: http://www.ansi.org or by calling 301-587-8202.

NOTE: Refer to the latest revision of each ANSI or ISO Standard specified.
Image structure

**Resolving power:** Based on recommended process.

<table>
<thead>
<tr>
<th>Film</th>

![Graph](image2)
Modulation transfer function

The MFT curve was determined using a method similar to that described in ANSI PH2.39-1977 (R1990), *Photographic Modulation Transfer Function of Continuous-Tone Black-and-White Photographic Films, Method of Measuring*.

Diffuse RMS granularity

Determined at a net diffuse density of 1.00, using the aperture indicated.

<table>
<thead>
<tr>
<th>48-Micrometer Aperture Value</th>
<th>48-Micrometer Aperture Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2462</td>
<td>5</td>
</tr>
<tr>
<td>2468/3468</td>
<td>less than 5</td>
</tr>
<tr>
<td>2470</td>
<td>less than 5</td>
</tr>
</tbody>
</table>

These values represent 1,000 times the standard deviation of density produced by the granular structure of the material when a uniformly exposed and developed sample is scanned with a densitometer calibrated to read American Standard diffuse visual density, and having a circular measuring aperture with the indicated diameter.

Granularity is an objective measurement of the spatial variation of sample density that generally correlates with graininess, which is the subjective effect of the image nonuniformity upon an observation when comparisons are made at the same density level.

Broadly speaking, granularity measurements with the 48-micrometer aperture will indicate the magnitude of the graininess sensation produced by viewing the diffusely illuminated sample with 12X monocular magnification.

NOTE: If the viewing conditions are changed from the specified conditions, the published RMS values may no longer correctly indicate the relative sensations of graininess produced by various samples.
